To M. MPF (Maturation Promoting Factor) includes the CdK and cyclins that triggers progression through the cell cycle. p53 is a protein that functions to block the cell cycle if the DNA is damaged. If the DNA is damaged, p53 activates p21, which inhibits the CdK/cyclin complex, preventing the cell from entering S phase. This allows time for DNA repair or, if the damage is irreparable, p53 can initiate apoptosis.

Mitosis and the cell cycle: The cell cycle is the series of events that occur in dividing cells between the completion of one mitotic division and the completion of the next division. Mitosis occupies only a small proportion of the whole cell cycle. The time taken to complete a cell cycle is called the cell cycle time.

The cell cycle, mitosis, and meiosis: The cell cycle is a repeating series of events that include growth, DNA synthesis, and cell division. The cell cycle in prokaryotes is quite simple: the cell grows, its DNA replicates, and the cell divides. In eukaryotes, the cell cycle is more complicated. Eukaryotic cell cycle: The diagram in Figure 12.1 shows the eukaryotic cell cycle. It consists of interphase, mitosis, and cytokinesis. Interphase is the longest part of the cell cycle and is divided into G<sub>1</sub>, S, and G<sub>2</sub> phases. During G<sub>1</sub>, the cell grows and prepares for DNA synthesis. During S, DNA is replicated. During G<sub>2</sub>, the cell grows again and prepares for mitosis. Mitosis is the process of cell division that results in two daughter cells. Cytokinesis is the process of dividing the cytoplasm and organelles between the two daughter cells.
